A PRACTICAL WEBSITE AND WORKFLOW COMPARISON

MommyCare vs Sashley Nannies

Both websites help Nairobi families explore homecare services. The clearest difference is the scope of the online experience and the backend workflows included in the MommyCare project.

AREA	MOMMYCARE	SASHLEY NANNIES
Website approach	Interactive website with a searchable directory, forms, and admin interface, connected to backend services.	Public website presents the agency, services, vetting information, sample profiles, and contact routes.
Finding care	Browse and filter professionals by role, Nairobi area, care arrangement, and selected skills.	Service pages describe nanny and household-staff options; sample profiles include links to ask about a provider.
Household enquiries	Booking and contact journeys send structured enquiries to backend endpoints for follow-up.	Public calls to action lead to consultation/contact routes and WhatsApp.
Urgent requests	A separate urgent-request flow captures details for team follow-up. A request is not a confirmed dispatch.	Contact and WhatsApp are published. A separate urgent-request form was not evident on the public pages reviewed.
Provider applications	Online application collects professional details and supporting documents for review.	The public "Apply for a Job" link leads applicants to WhatsApp.
Admin and documents	Project includes admin review tools. Provider documents are designed for private storage and authorized review.	Internal application review, document handling, and coordinator tools are not verifiable from the public site.
Additional content	Also includes salary guidance, reviews, childcare insights, academy content, and policy pages.	Publicly focuses on agency and service information, vetting, careers, contact, and FAQs.

Public-site review: sashleynannies.co.ke. This compares visible website features; it does not assess either agency’s service quality.

BACKEND SCOPE BEYOND A BROCHURE WEBSITE

Why the implementation takes longer

A static marketing site and a backend-enabled service site are different builds.

A marketing site mainly presents information and directs visitors to contact the business. MommyCare includes those public pages, plus software that captures, stores, and helps staff manage household and provider information.

Connected forms

Booking, contact, and urgent-request submissions must validate correctly, reach the backend, and show a clear success or error state.

Provider applications

Application details and supporting files must be captured and associated correctly, rather than disappearing into an untracked message.

Privacy and access

Personal information and identity documents need appropriate storage and access controls; public pages must not expose private records.

Coordinator tools

Staff need workflows to find submissions, review applications, update statuses, and follow up with families and applicants.

End-to-end testing

The browser, API, database, file storage, and admin workflow must work together, including failure cases and production configuration.

A client-ready summary

"Sashley is a useful reference for a clear nanny-agency website. MommyCare is being built with a broader digital workflow: families can explore staff and submit structured requests, professionals can apply with supporting documents, and coordinators can manage submissions through admin tools. Building and testing those connected journeys takes more time than building static pages alone. Backend features still need production-like end-to-end validation before every workflow can be called launch-ready."

Accuracy note: Sashley's public pages show service information and contact/WhatsApp routes. Its private backend or internal operations cannot be determined from those pages. MommyCare capabilities described here are present in the project; production readiness depends on configuration and testing.
